

**Description**

Power-One's high power modular products can be configured to provide up to 21 outputs in over 10 million voltage and current combinations. Eighteen chassis are available from 1000 to 4000 watts; including power factor corrected, three-phase input, and metric mounting hardware models. Over 90 output modules are available to provide voltages from 1 to 48VDC. Output modules have a field demonstrated MTBF of greater than 5 million hours. Other features include a comprehensive array of module and system interface signals, extensive input transient protection, and international regulatory agency approvals. These high-performance products have a proven track record in high reliability communications, semiconductor test, and industrial applications.

NUCLEAR AND MEDICAL APPLICATIONS - Power-One products are not designed, intended for use in, or authorized for use as critical components in life support systems, equipment used in hazardous environments, or nuclear control systems without the express written consent of the respective divisional president of Power-One, Inc.

TECHNICAL REVISIONS - The appearance of products, including safety agency certifications pictured on labels, may change depending on the date manufactured. Specifications are subject to change without notice.

## PRODUCT OVERVIEW

### RELIABILITY

- Demonstrated DC output module MTBF of greater than 5 million hours.
- Ruggedized AC input sections incorporate extensive transient protection.
- Vibration tested at 6 GRMS, 3 axis, 10 to 2000 Hz.
- Two-year warranty.

### FLEXIBILITY

- Modular construction; over 10 million configurations available.
- Up to 21 outputs per power supply from 1.0 to 48 VDC.
- Parallelable outputs with current sharing.
- System inhibit and individual module output inhibit capability.
- Metric mounting available on selected models.

### PERFORMANCE

- Single outputs fully regulated and isolated.
- Active PFC models meet EN61000-3-2 and EN60555-2.
- EN60950/UL1950 approved. CE Marked to the Low Voltage Directive.
- No minimum loads required on most outputs.

### Modular High Power Series Product Overview

**MODULAR SYSTEM OVERVIEW AND SELECTION**

**Modular System Overview**

Power-One's Modular High Power Series products are configured with separate switch-mode DC output modules to provide the voltage and current ratings required by each specific application.

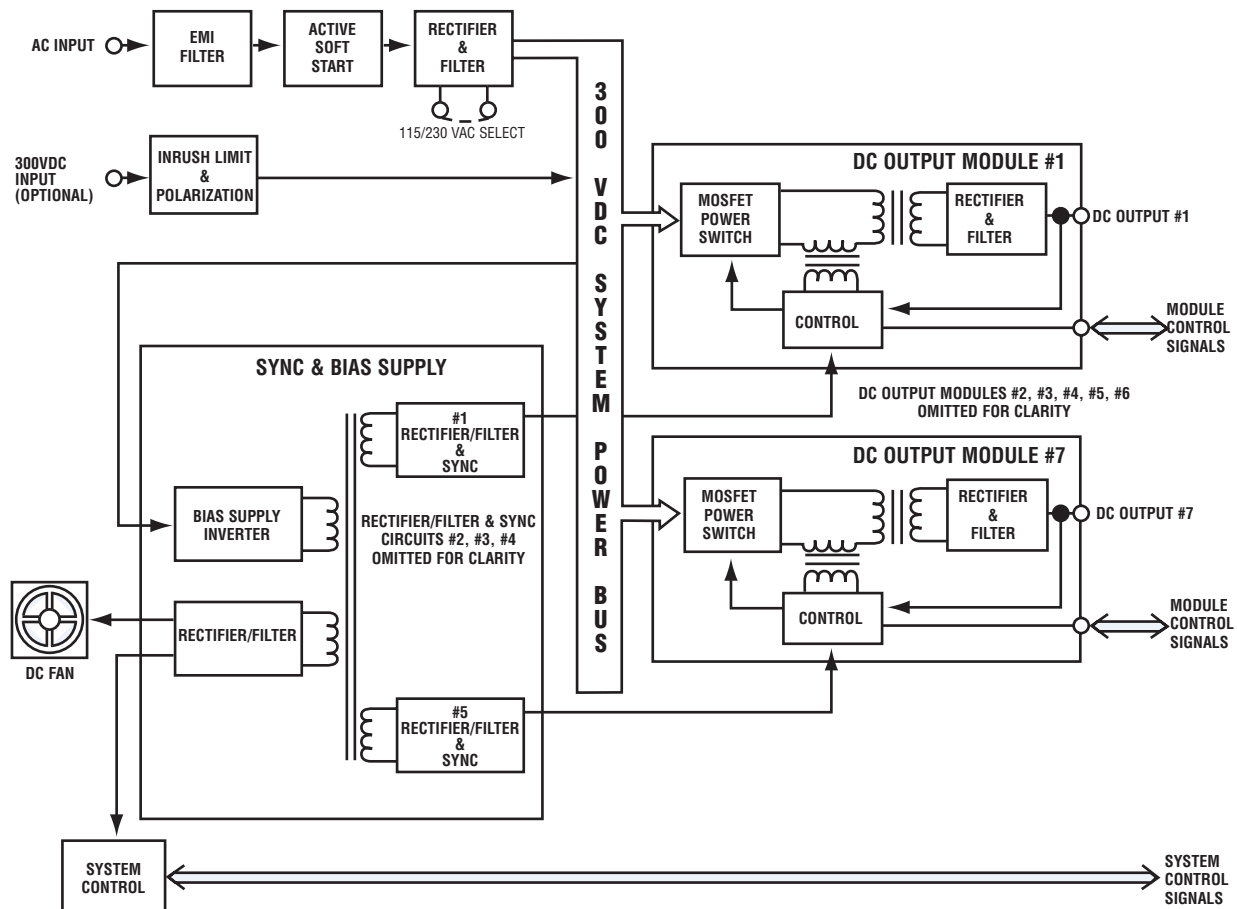

The system is based on a 300 VDC system power bus derived from either the AC utility line, or a user-supplied 300 VDC source. This 300 VDC bus provides the bulk DC required by each output module for conversion to its specified output voltage and current ratings.

As shown in the block diagram, this independent modular approach provides complete isolation between the outputs, as well as all other system elements. Also, the switching circuitry of each output module is clocked and synchronized by the sync & bias supply section to reduce electrical interference between the outputs.

**Selection**

The modularity of these high power products allows the user to specify a power system configured from a wide selection of standard off-the-shelf, plug-in modules. The power system is delivered completely assembled, burned in, and tested. A part number comprised of a series designation, module listing, and options can be configured as follows:

1. Choose a chassis based on required wattage, number of outputs, and power factor.
2. Select modules following the guidelines in the configuration section.
3. Decide on the options. Standard options are listed in the configuration section. Please call the factory for special requirements, such as logic option cards.

## CONFIGURATION NOTES AND OPTIONS

### Configuration Notes

- Modules are designated left to right in the part number but are installed right to left in the chassis.
- Single and double wide modules occupy one and two chassis slots, respectively. Confirm that the total number of slots required does not exceed the chassis slot capacity.
- Not all modules can be used in all slots. Refer to the compatibility table below.
- Fill blank slots with K or L option.

**EXAMPLE:** OUTPUTS SELECTED    5V @ 150A  
     12V @ 20A  
     -12V @ 20A

All chassis slots are numbered in right-to-left sequence

### Standard Options

SYSTEM INHIBIT (OPT A, B & C)			INPUT POWER FAIL WARNING (OPT M, N & P)		OTHER OPTIONS
POWER OUTPUT			OPTION	SIGNAL OUTPUT	DESCRIPTION
Std	Logic Low	Open Ckt. or Logic High	Std	+5V  Hi To Lo Transition	K – Single-Width Slot Blank L – Double-Width Slot Blank  See Paralleled Module Configurations on Page 8 for Additional Options
A	Logic High	Open Ckt. or Logic Low	N	 Open Collector Conducts To Give Signal	
B	Open Ckt. or Logic High	Logic Low	M	+5V  Lo To Hi Transition	
C	Open Ckt. or Logic Low	Logic High	P	 Open Collector Opens To Give Signal	

### Module and Chassis Compatibility

Confirm that the number listed in the compatibility column of the module selector guide is equal to or less than the lowest number specified for the module slots pictured below. Example: The SPF3 can only use modules with a

slot compatibility of 1 in the slot closest to the input section, but can use any module with a compatibility number of four or less in the other two slots. Bold lines designate adjoining slots that can be used for double wide modules.

- NOTES:**
- A) For ambient temperatures above 50 °C, output current must be linearly derated to 50% at the maximum operational ambient temperature, 70 °C.
  - B) The output noise and ripple measurement is bandwidth limited to 20 MHz.
  - C) Module is designed to accommodate output cable losses of up to one volt.
  - D) A4 module provides 220A in chassis with slot compatibility rating of 3, and 250A in chassis with slot compatibility rating of 4.
  - E) Module is designed for use in applications demanding low noise and ripple. Consult factory for further specifications.
  - F) Not to be used with SPM2 and SPM3 chassis.
  - G) All triple output modules, as well as the M4 dual-output module, have floating outputs. Like voltages may be shared within the same module. All triple output adjustments and interface signals are for output #1. Consult factory for more information.
  - H) The dedicated negative (-) output is quasi-regulated. Both outputs require a small minimum load to perform to specification. Consult factory for more information.

Modules that are highlighted in yellow or shaded are not recommended for new designs.

## PARALLELED MODULE CONFIGURATIONS

Single output, similar-voltage output modules can be configured for parallel operation to provide output currents up to 840 amps. Factory standard paralleling suffixes are shown below. All paralleling suffixes include factory-installed bus bars and internally-connected current sharing. Please consult factory for paralleling configurations not shown.

- Choose appropriate chassis and modules as described in the Selection and Configuration Notes sections.
- Select the required output connection type as shown in the Module Selector Guide.
- Select the paralleling suffix that corresponds to the selected output modules. (The paralleling suffix follows after all other option codes.)

- Select Modules: A4 (5V @ 250A), A6 (5V @ 60A)
- Choose Corresponding Paralleling Suffix: YD
- Final Part Number: HPF3A4A6YD

### LIMITATIONS FOR STANDARD PARALLELING SYSTEM

- Single output modules only
- Ripple and noise limit will be 20% over the largest value paralleled
- For paralleling modules over 320A, consult factory

### OUTPUT CONNECTIONS

Type I = #10-32 studs  
Type II = Barrier Block  
Type III = 5/16"-18 studs

**DC OUTPUT MODULE SPECIFICATIONS**

**SINGLE AND DUAL OUTPUT MODULES**

PARAMETER	CONDITIONS/DESCRIPTION	MIN	NOM	MAX	UNITS
Output Voltage Adjustment Range	(V2 output is not adjustable)	-10		+10	%

## **EXCEPTIONAL AC INPUT TRANSIENT IMMUNITY**

### **Initial Analysis**

Power-One has been working with customers to improve our high power products for over ten years. Because these products are often used in industrial environments, some of our customers were concerned with AC input transient immunity. This prompted us to implement an extensive data collection and analysis project which provided the following information:

- 1) AC input monitoring data taken at end-users (our customers' customers) sites revealed extreme input transients with differential transients beyond the highest levels, and longest durations, of the new ISO1000/EN61000-4-5 specification.
- 2) A review of our failure analysis database revealed primary-side component failures which appeared to be caused by excessive input transients. In addition, some customers reported similar failures with high power products manufactured by companies other than Power-One.
- 3) The AC input monitoring data, mentioned in item #1, was used as a starting point in engineering lab testing and Spice modeling. Both methodologies confirmed the failure modes mentioned in item #2.

### **Other Factors**

Given the very high demonstrated MTBF hours of the DC output modules, failures that were thought to be caused by AC input line transients became a significant percentage of overall customer returns. Therefore, the plan to enhance overall reliability included increasing the robustness of the AC input section.

We found that AC input transient immunity is most critical to equipment that is not powered from a standard 115VAC wall socket, and where line impedances (resistive and inductive) are relatively high, and aid in the absorption of transient line conditions. Experience has also shown that the primary cause of damage is differential voltage events (between the lines), not common mode (between line(s) and ground).

**EXCEPTIONAL AC INPUT TRANSIENT IMMUNITY**

**Improvements**

Enhancing the input board design was accomplished by specifying oversized input components and adding Metal Oxide Varistors (MOV's) to protect against both common and differential-mode transients. Before putting the enhanced input board into production, an extensive qualification program was performed which confirmed that the following standards were exceeded:

<b>Specification</b>	<b>Description</b>	<b>Classification</b>	<b>Volts</b>
EN61000-4-2	ESD Immunity	Level 4	8kV
EN61000-4-3	RF Susceptibility	Level 3	10V/m
EN61000-4-4	Fast Transient/Burst Immunity	Level 3	4kV
EN61000-4-5	Surge Immunity		
	Common-mode	Class 4	4kV
	Differential-mode	Class 4	2kV

It is important to note that these are the most stringent levels of each of these specifications. In the case of the critical differential surge immunity level, Power-One's internal design and test levels for high power products are over twice the maximum specification level shown above.

**Field Data Results**

The field data results were impressive. After a year, and over 10,000 units shipped with enhanced AC input sections, our customers have not returned any products that were diagnosed to have AC input transient related failures. This clearly shows that we have significantly improved the field reliability of our high power products and have set a new standard in the industry for AC input transient immunity.

To complement the robustness of the AC input chassis, the DC output modules have a demonstrated MTBF of over 5 million hours. The next three pages describe how the exceptional MTBF of the DC output modules also contributes to making Power-One's high power products the most reliable in the industry.

## DC OUTPUT MODULES DEMONSTRATED MTBF OF 5 MILLION HOURS

### Overview

This report summarizes the methodology, calculations, and results that were used to document the field reliability of standard high power product modules (non-RPM5), and to predict the reliability of the enhanced performance high density modules for the 4,000 Watt RPM5 Series power supply. Based on this data, the typical output module demonstrated MTBF is five million hours with an ambient temperature of 25 °C.

### Basis for Prediction

At the beginning of 1996, Power-One initiated the design of the 4,000 Watt RPM5. This design project produced one of the highest power density AC/DC power supplies in the industry. To support this program, Power-One started an extensive effort to update field reliability information for existing (non-RPM5) modules. In addition to quantifying the reliability for these modules, this information was also used as the basis for predicting the reliability of the new high density RPM5 module designs.

Power-One created a 33-page proprietary report analyzing the field history (by power supply, by module), utilizing years of data. The customer's end-product used in this report operated 24 hours per day, 7 days per week, and accumulated over 140 million unit-hours of field data for this analysis. In addition, three years of field failure data were gathered from Power-One's on-line failure analysis database. Power-One believes this actual demonstrated field history is more valuable and provides a more realistic reliability estimation than that represented by the theoretical calculated predictions of MIL-HDBK-217 or Bellcore TR-332.

### Methodology

The minimum and maximum MTBF (80% confidence level) was established by applying the Chi-Squared method to the collected data. To improve the usefulness of the results in the original report, this report includes similar modules (same/similar PCB and mechanical structure). In the case of the RPM5 Series modules, the respective base module data was used as a starting point and was then modified to reflect new stress levels, new components, modified cooling, etc.

### Results

The data on the following pages present the resulting field reliability of 48 modules. This data includes minimum and maximum FITs (Failures In Time -  $10^9$  hours) and MTBF at 25 °C for each of the modules.

**Vibration testing** is performed in three orthogonal axis from 10 to 2000 Hz, at 6.15 GRMS as part of STRIFE testing.

**Thermal shock testing** includes a 15 °C per minute ramp rate from -30 °C to +80 °C while input power is cycled and outputs are driven to full-rated load. This is also a part of STRIFE testing.

**DC OUTPUT MODULES DEMONSTRATED MTBF OF 5 MILLION HOURS**

**Details of MTBF Information**

Please refer to the table on the following page for MTBF data for specific modules.

Field data included:

- 3 year shipment history
- 19 unique power supply configurations
- 21 types of output modules
- 4 million to 71 million operating hours for individual modules

Data adjustments were objectively made to:

- Eliminate customer induced and other similar failures
- Provide for confidence factors (80%)
- Eliminate non-operating time prior to installation
- Group similar modules with similar failure rates to improve accuracy of data
- Make minor extrapolations for modules that had minor technical variations from subject modules

**Computer Aided Design (CAD)** provides thermal modeling, vibration analysis, and circuit simulation data before a prototype is built. Extensive use of computer-based modeling programs contributes to reliability.

Power-One's modular products have been proven in high-reliability communications and semiconductor test equipment applications.

## High Power DC Output Module Reliability
